# 1. Fortran Pointers

- A pointer is a variable that points at a variable of some type: elementary, or derived types. (but not pointers)
- You can access and change the value of a variable through a pointer that points at it.
- You can change what variable the pointer points at.
- A pointer acts like an alias:  
no explicit dereference needed.

## 2. Setting the pointer

- You have to declare that a variable is pointable:

```
real,target :: x
```

- Declare a pointer:

```
real,pointer :: point_at_real
```

- Set the pointer with => notation (New! Note!):

```
point_at_real => x
```

### 3. Dereferencing

Fortran pointers are often automatically *dereferenced*: if you print a pointer you print the variable it references, not some representation of the pointer.

Code:

```
real,target :: x
real,pointer :: point_at_real

x = 1.2
point_at_real => x
print *,point_at_real
```

Output

[pointerf] basicp:

1.20000005

## 4. Pointer example

Code:

```
real,target :: x,y
real,pointer :: that_real

x = 1.2
y = 2.4
that_real => x
print *,that_real
that_real => y
print *,that_real
y = x
print *,that_real
```

Output

[pointerf] realp:

1.20000005

2.40000010

1.20000005

1. *that\_real* points at *x*, so the value of *x* is printed.
2. *that\_real* is reset to point at *y*, so its value is printed.
3. The value of *y* is changed, and since *that\_real* still points at *y*, this changed value is printed.

## 5. Assign pointer from other pointer

```
real, pointer :: point_at_real, also_point  
point_at_real => x  
also_point => point_at_real
```

Now you have two pointers that point at x.

**Very important to use the =>, otherwise strange memory errors**

## 6. Assignment subtleties

What happens if you want to write  $p2 \Rightarrow p1$   
but you write  $p2 = p1$ ?

The second one is legal, but has different meaning:

Assign underlying variables:

```
real, target :: x, y
real, pointer :: p1, p2

x = 1.2
p1 => x
p2 => y
p2 = p1 ! same as y=x
print *, p2 ! same as print y
```

Crash because  $p2$  pointer  
unassociated:

```
real, target :: x
real, pointer :: p1, p2

x = 1.2
p1 => x
p2 = p1
print *, p2
```

## 7. Pointer status

- Nullify: zero a pointer
- Associated: test whether assigned

Code:

```
real,target :: x
real,pointer :: realp

print *, "Pointer starts as not set"
if (.not.associated(realp)) &
    print *, "Pointer not associated"
x = 1.2
print *, "Set pointer"
realp => x
if (associated(realp)) &
    print *, "Pointer points"
print *, "Unset pointer"
nullify(realp)
if (.not.associated(realp)) &
    print *, "Pointer not associated"
```

Output

[pointerf] statusp:

```
Pointer starts as
not set
Pointer not
associated
Set pointer
Pointer points
Unset pointer
Pointer not
associated
```

## 8. Pointer allocation

If you want a pointer to point at something,  
but you don't need a variable for that something:

Code:

```
Real,pointer :: x_ptr,y_ptr  
allocate(x_ptr)  
y_ptr => x_ptr  
x_ptr = 6  
print *,y_ptr
```

Output

[pointerf] allocptr:

6.00000000

(Compare `make_shared` in C++)

# Exercise 1

Write a routine that accepts an array and a pointer, and on return has that pointer pointing at the largest array element:

Code:

```
real,dimension(10),target :: array &  
    = [1.1, 2.2, 3.3, 4.4, 5.5, &  
        9.9, 8.8, 7.7, 6.6, 0.0]  
real,pointer :: biggest_element  
  
print '(10f5.2)',array  
call SetPointer(array,biggest_element)  
print *, "Biggest element  
    is",biggest_element  
print *, "checking pointerhood:",&  
    associated(biggest_element)  
biggest_element = 0  
print '(10f5.2)',array
```

Output

[pointerf] arpointf:

```
1.10 2.20 3.30 4.40  
5.50 9.90 8.80  
7.70 6.60 0.00
```

Biggest element is  
9.89999962

checking

```
pointerhood: T  
1.10 2.20 3.30 4.40  
5.50 0.00 8.80  
7.70 6.60 0.00
```

*You can base this off the file arpointf.F90 in the repository*

## 9. Linked list

- Linear data structure
- more flexible than array for insertion / deletion
- ... but slower in access

# Linked list

# Insertion

## 10. Linked list datatypes

- Node: value field, and pointer to next node.
- List: pointer to head node.

```
type node
  integer :: value
  type(node), pointer :: next
end type node
```

```
type list
  type(node), pointer :: head
end type list
```

# 11. Sample main

Our main program will create three nodes, and append them to the end of the list:

Code:

```
type(list) :: the_list
type(node),pointer :: node_ptr

nullify(the_list%head)

allocate(node_ptr); node_ptr%value = 1
call attach(the_list,node_ptr)
allocate(node_ptr); node_ptr%value = 5
call attach(the_list,node_ptr)
allocate(node_ptr); node_ptr%value = 3
call attach(the_list,node_ptr)

call print(the_list)
```

Output

[pointerf] listappend:

List: [ 1,5,3, ]

## 12. List initialization

```
subroutine attach( the_list,new_node )  
  implicit none  
  ! parameters  
  type(list),intent(inout) :: the_list  
  type(node),intent(inout),pointer :: new_node
```

First element becomes the list head:

```
! if the list has no head node, attached the new node  
if (.not.associated(the_list%head)) then  
  nullify(new_node%next)  
  the_list%head => new_node  
else
```

## 13. Attaching a node

New element attached at the end.

```
! go down the list, finding the last node  
current => the_list%head  
do while ( associated(current%next) )  
    previous => current  
    current => current%next  
end do  
nullify(new_node%next)  
current%next => new_node
```

(This is the iterative solution; you can also do it recursively.)

## 14. Main for inserting

Almost the same as before,  
but now keep the list sorted:

Code:

```
allocate(node_ptr); node_ptr%value = 1  
call insert(the_list,node_ptr)  
allocate(node_ptr); node_ptr%value = 5  
call insert(the_list,node_ptr)  
allocate(node_ptr); node_ptr%value = 3  
call insert(the_list,node_ptr)  
call print(the_list)
```

Output

[pointerf] listinsert:

List: [ 1,3,5, ]

## Exercise 2

Copy the *attach* routine to *insert*, and modify it so that inserting a node will keep the list ordered.

*You can base this off the file `listfininsert.F90` in the repository*

## Exercise 3

Modify your code from exercise 2 so that the new node is not allocated in the main program. Instead, pass only the integer argument, and use `allocate` to create a new node when needed.

```
call insert(the_list,1)
call insert(the_list,5)
call insert(the_list,3)
```
